beam-package   *Fast Bayesian Inference in Large Gaussian Graphical Models*

Description

The package enables inference of marginal and conditional dependencies from high-dimensional
using the method of Leday and Richardson (2019). Inference is carried out by multiple testing of
hypotheses about pairwise (marginal or conditional) independence using closed-form Bayes factors.
Exact tail probabilities are obtained from the null distributions of the Bayes factors to help address
the multiplicity problem and control desired error rates for incorrect edge inclusion. The method
is computationally very efficient and allows to address problems with hundreds or thousands of
variables.

Details

1. The main function of the package is `beam` which carries out shrinkage estimation of the (inverse)
covariance and compute the (scaled) Bayes factors as well as the tail probabilities (p-values). The
function returns an (S4) object of class `beam-class` that is associated with the following methods:

- `summary,beam-method`:
provides a summary of inferred (marginal and/or conditional) associations.

- `marg,beam-method`:
returns a data.frame with marginal correlations, Bayes factors and/or tail probabilities.

- `cond,beam-method`:
returns a data.frame with partial correlations, Bayes factors and/or tail probabilities.

- `mcor,beam-method`:
return marginal correlation matrix (scaled posterior expectation of the covariance matrix).

- `pcor,beam-method`:
return partial correlation matrix (scaled posterior expectation of the inverse covariance matrix).

- `plotML,beam-method`:
plot log-marginal likelihood of the Gaussian conjugate model as a function of shrinkage parameter.

- `plotCor,beam-method`:
plot heatmap of marginal (upper triangle) and/or partial (lower triangle) correlation estimates.

2. The function `beam.select` takes as input an object of class `beam-class` and carries out edge
selection by multiple testing of hypotheses about pairwise (marginal or conditional) independence.
The function helps address the multiplicity problem and control different types of error rates (e.g.
false discovery rate, family-wise error rate, ...). `beam.select` returns an (S4) object of class
`beam.select-class` that is associated with the following methods:

- `summary,beam.select-method`:

provides a summary of inferred (marginal or conditional) associations.

- `marg,beam.select-method`:

returns a data.frame with marginal correlations, Bayes factors and/or tail probabilities for selected edges.

- `cond,beam.select-method`:

returns a data.frame with partial correlations, Bayes factors and/or tail probabilities for selected edges.

- `bgraph,beam.select-method`:

return an igraph object containing the marginal (in)dependence graph.

- `ugraph,beam.select-method`:

return an igraph object containing the conditional (in)dependence graph.

beam	*Bayesian inference in large Gaussian graphical models*

Description

This function carries out covariance and inverse covariance estimation within the Gaussian conjugate model. The scale matrix parameter of the inverse-Wishart is set to the identity (default), whereas the degree of freedom parameter is estimated by maximization of the marginal likelihood. The function also computes the Bayes factor and tail probability (p-values) to test the marginal or conditional independence between all pairs of variables.

Usage

```
beam(X, type = "conditional", return.only = c("cor", "BF", "prob"),
verbose=TRUE, D=NULL)
```

Arguments

X	n by p data matrix
type	character. Either "marginal", "conditional" or "both". See Details.
return.only	character. Either "cor", "BF", "prob". See details.
verbose	logical. Whether information on progress should be be printed.
D	matrix. Prior marginal correlation matrix. Must be positive definite, well-conditioned and have unit variance.

Details

The arguments `type` and `return.only` have essentially been introduced for computational and memory savings. Using argument `type` the user may indicate whether the marginal dependencies ("marginal"), the conditional dependencies ("conditional") or both ("both") are to be inferred. On the other hand, the argument `return.only` is used to indicate whether the correlations ("cor"), Bayes factors ("BF") or tail probabilities ("prob") should be returned. Default is to return all three quantities for conditional dependencies.

Value

An object of class `beam-class`

Author(s)

Gwenael G.R. Leday and Ilaria Speranza

References

Examples

```
# Load data
data(TCPAprad)

# beam
fit <- beam(X = TCPAprad, type="both")

# Print summary
summary(fit)

# Extract matrix of marginal correlations
mcor(fit)[1:5, 1:5]

# Extract matrix of partial correlations
pcor(fit)[1:5, 1:5]

# Plot log-marginal likelihood of the Gaussian conjugate model
plotML(fit)

# Plot heatmap of marginal (upper triangle) and/or
# partial (lower triangle) correlation estimates
plotCor(fit)
```

---

beam-class   *Class beam*

Description

An S4 class representing the output of the beam function.

Usage

```
   ## S4 method for signature 'beam'
print(x, ...)

   ## S4 method for signature 'beam'
show(object)

   ## S4 method for signature 'beam'
summary(object, ...)

   ## S4 method for signature 'beam'
marg(object)

   ## S4 method for signature 'beam'
cond(object)

   ## S4 method for signature 'beam'
mcor(object)

   ## S4 method for signature 'beam'
pcor(object)

   ## S4 method for signature 'beam'
postExpSigma(object, vars.method="eb")

   ## S4 method for signature 'beam'
postExpOmega(object, vars.method="eb")

   ## S4 method for signature 'beam'
plotML(object, ...)

   ## S4 method for signature 'beam'
plotCor(object, type = object@type, order = 'original', by = "marginal")

   ## S4 method for signature 'beam'
bgraph(object)

   ## S4 method for signature 'beam'
ugraph(object)
```

Arguments

x	An object of class `beam-class`
object	An object of class `beam-class`
type	character. Type of correlation to be displayed (marginal, conditional or both)
order	character. Either 'original' or 'clust'. If 'clust' the rows and columns of the correlation matrix are reordered using the cluster memberships obtained by the Louvain clustering algorithm.
by	character. When type ="both" and order = 'clust', specifies whether the clustering has to be performed using the complete weighted marginal or conditional independence graph.
vars.method	character. Method of shrinkage estimation for the variances. Either 'eb', 'mean', 'median' for shrinkage estimation of variance respectively towards an estimated shrinkage target, the mean or the median of the sample variances. Choosing 'none' carries out no shrinkage and uses the sample variances, whereas choosing 'scaled' means that the sample covariance has unit diagonal.
...	further arguments passed to or from other methods.

Slots

table dat.frame. A data.frame containing marginal and/or partial correlation estimates, Bayes factors and tail probabilities for each edge.

deltaOpt numeric. Empirical Bayes estimate of hyperparameter delta.

alphaOpt numeric. Empirical Bayes estimate of hyperparameter alpha.

dimX numeric. Dimension of the input data matrix X.

type character. Input argument.)

varlabs character. Column labels of X.

gridAlpha matrix. A matrix containing the log-marginal likelihood of the Gaussian conjugate model as a function of a grid of values of alpha and delta.

valOpt numeric. Maximum value of the log-marginal likelihood of the Gaussian conjugate model.

return.only character. Input argument.

time numeric. Running time (in seconds).

TinvStdev numeric. Square root of partial variances.

s numeric. Sample variances.

rzij numeric. Statistics.

beam.select   *Edge selection with multiple testing and error control*

Description

Infer graphical structures by multiple testing

Usage

```
beam.select(object, thres = 0.1, method = "BH",
return.only = c(object@return.only, "adj"))
```

Arguments

object	An object of class [beam-class]().
thres	numeric. Threshold to be applied on adjusted tail probabilities.
method	character. Method to use for multiple comparison adjustment of tail probabilities.
return.only	character. Quantities to be returned.

Details

The argument `method` allows to adjust the tail probabilities obtained from the null distributions of the Bayes factors for multiple comparisons. Possible choices are: "holm", "bonferroni", "BH", "BY" and "HC". Apart from "HC", these are passed onto the R function `p.adjust` from package **stats** and we refer the user to its documentation for details. The method "HC" provides an optimal decision threshold based on the Higher Criticism score which is computed using the R function `hc.thresh` from package **fdrtool**. Again, we refer to the associated documentation for details.

The argument `return.only` allows to decide which quantities have to be in the output: it could be any subvector of c('cor', 'BF', 'prob', 'adj') (provided that the requested quantities have been computed in the beam object, except for adjusted probabilities). It can also be set to NULL: in this case, only the selected edges will be returned without any additional information. The default value for this argument are the columns present in the beam object plus the adjusted probabilities.

Value

An object of class [beam.select-class]()

beam.select-class   *Class beam.select*

Description

An S4 class representing the output of the beam.select function.

Usage

```
  ## S4 method for signature 'beam.select'
print(x, ...)

  ## S4 method for signature 'beam.select'
show(object)

  ## S4 method for signature 'beam.select'
summary(object, ...)

  ## S4 method for signature 'beam.select'
marg(object)

  ## S4 method for signature 'beam.select'
cond(object)

  ## S4 method for signature 'beam.select'
mcor(object)

  ## S4 method for signature 'beam.select'
pcor(object)

  ## S4 method for signature 'beam.select'
plotML(object, ...)

  ## S4 method for signature 'beam.select'
plotAdj(object, type=object@type, order = "original")

  ## S4 method for signature 'beam.select'
```

```
bgraph(object)

  ## S4 method for signature 'beam.select'
ugraph(object)
```

Arguments

x	An object of class `beam.select-class`
object	An object of class `beam.select-class`
type	character. Type of correlation to be displayed (marginal, conditional or both)
order	character. Either 'original' or 'clust'. If 'clust' the rows and columns of the adjacency matrix are reordered using the cluster memberships obtained by the Louvain clustering algorithm.
...	further arguments passed to or from other methods.

Slots

`marginal` data.frame. A data.frame containing the marginal correlation estimates, Bayes factors and tail probabilities for the selected edges only.

`conditional` data.frame. A data.frame containing the partial correlation estimates, Bayes factors and tail probabilities for the selected edges only.

`dimX` numeric. Dimension of the input data matrix X.

`type` character. Input type (marginal, conditional or both)

`varlabs` character. Column labels of X.

`alphaOpt` numeric. Empirical Bayes estimates of hyperparameter alpha.

`gridAlpha` matrix. A matrix containing the log-marginal likelihood of the Gaussian conjugate model as a function of a grid of values of alpha and delta.

`valOpt` numeric. Maximum value of the log-marginal likelihood of the Gaussian conjugate model

`method` character. Input method.

`thres` numeric. Input threshold

---

lightbeam   *Fast inference of a conditional independence graph*

Description

Fast and memory efficient reconstruction of large conditional independence networks.

Usage

```
lightbeam(X, thres = 0.1, method = "holm", verbose=TRUE)
```

Arguments

X	n by p data matrix
thres	numeric. Significance threshold to be applied on adjusted tail probabilities.
method	character. Method to use for multiple comparison adjustment of tail probabilities.
verbose	logical. Whether information on progress should be be printed.

Details

The function returns a sparse upper triangular matrix containing the (adjusted) tails probabilities that are below the given threshold (i.e. significant).

Value

An object of class `dgCMatrix-class`

Examples

```
# Load data
data(TCPAprad)

# beam
res <- lightbeam(X = TCPAprad, thres=0.1)
```

TCPAprad   *Protein expression data.*

Description

Level 3 normalized proteomic data (v3.0) from The Cancer Proteome Alas (http://tcpaportal.org/tcpa). The data comprise the measurements of 189 antibodies obtained from 164 tumor tissue samples (prostate adenocarcinoma) using reverse phase protein arrays (RPPA).

Usage

```
TCPAprad
```

Format

A 164 by 189 matrix
